

## 2. Klassen in C++

wenn ein nutzedefinierter Copy-Konstruktor vorliegt, ist zumeist auch der Zuweisungsoperator nutzerdefiniert zu implementieren

```
Stack& Stack::operator= (const Stack& src)
{
    if (&src==this) return *this; // self assignment
    top = src.top;
    max = src.max;
    // NOT: data = src.data; as the implicit one does
    // leak in this->data, data sharing afterwards
    delete[] data;
    data = new int[max];
    for (int i=0; i<top; ++i) data[i]=src.data[i];
    return *this;
}
```

## 2. Klassen in C++

Copy-Konstruktor und Copy-Assignment-Operator sind semantisch verwandt: meist gemeinsam bereitzustellen!

Kanonische und exception safe Implementation:

GotW #59 (Sutter: mxC++ Item 22)

What is the canonical form of strongly exception safe copy assignment?

## 2. Klassen in C++

### **What are the three common levels of exception safety? Briefly explain each one and why it is important.**

The canonical Abrahams<sup>(\*)</sup> Guarantees are as follows.

1. **Basic Guarantee**: If an exception is thrown, **no resources are leaked**, and **objects remain in a destructible and usable -- but not necessarily predictable -- state**. This is the weakest usable level of exception safety, and is appropriate where client code can cope with failed operations that have already made changes to objects' state.
2. **Strong Guarantee**: If an exception is thrown, **program state remains unchanged**. This level always implies global commit-or-rollback semantics, including that no references or iterators into a container be invalidated if an operation fails. In addition, certain functions must provide an even stricter guarantee in order to make the above exception safety levels possible:
3. **Nothrow Guarantee**: The function **will not emit an exception under any circumstances**. It turns out that it is sometimes impossible to implement the strong or even the basic guarantee unless certain functions are guaranteed not to throw (e.g., destructors, deallocation functions).

(<sup>\*</sup> [http://www.boost.org/more/generic\\_exception\\_safety.html](http://www.boost.org/more/generic_exception_safety.html))

## 2. Klassen in C++

### **Exception safe copy assignement → two steps:**

**First, provide a nonthrowing Swap() function that swaps the guts (state) of two objects:**

```
void T::Swap( T& other ) // throw()
{ /* ...swap the guts of *this and other... */ }
```

**Second, implement operator=() using the "create a temporary and swap" idiom:**

```
T& T::operator=( const T& other ) {
    T temp( other ); // do all the work off to the side
    Swap( temp );   // then "commit" the work using
                    // nonthrowing operations only
    return *this;
}
```

## 2. Klassen in C++

### Beispiel Stack: stack.h

```
class Stack {
    int max, top;
    int *data;
    void swap(Stack&); // throw ();

protected:
    int* get_data() const {return data;}
    int  get_top() const  {return top;}
    int  get_max() const  {return max;}
public:
    explicit Stack(int dim=100);
    Stack(const Stack&);
    Stack& operator=(const Stack&);

    virtual ~Stack();
    virtual void push (int i);
    int pop();
    int full() const;
    int empty() const;
};
```

## 2. Klassen in C++

### Beispiel Stack: stack.cc

```
//...
Stack::Stack(int dim): max(dim), top(0), data(new int[dim]) { }

Stack::Stack(const Stack& o):max(o.max),top(o.top),data(new int[o.max]) {
    for (int i=0; i<top; ++i) data[i] = o.data[i];
}

#include <algorithm>
void Stack::swap(Stack& other) {           // never fails:
    std::swap(max, other.max);            // swapping
    std::swap(top, other.top);            // builtin types
    std::swap(data, other.data);          // always succeeds
}

Stack& Stack::operator=(const Stack& src) {
    Stack temp (src); // in case of failure: no change to this
    swap(temp);       // succeeds always
    return *this;
}
//...
```

## 2. Klassen in C++

**const** reicht zur Unterscheidung von überladenen Funktionen (auch Operatoren) aus

typisches Idiom:

```
class Vector { int* data; int dim;
    void check(int i) const // WHY const?
    {if (i<0 || i>=dim) throw std::out_of_range("Vector");}
public:
    Vector(int d, int val=0): dim(d), data(new int[d])
    {for (int i=0; i<dim; ++i) data[i]=val;}
    Vector(const Vector&); // deep copy
    Vector& operator=(const Vector&); // deep assign
    int operator[] (int i) const { check(i); return data[i]; }
    int& operator[] (int i)      { check(i); return data[i]; }
};

const Vector cv(20, 3); int i = cv[11]; // NOT cv[11] = 3;
Vector v(20, 4); int j = v[13]; v[13] = 7;
```

## 2. Klassen in C++

### Nutzerdefinierte Ein- und Ausgabe

```
class SomeClass { ...
```

```
friend std::ostream& operator<<
```

```
(std::ostream&, [const] SomeClass [&]);
```

```
friend std::istream& operator>>
```

```
(std::istream&, SomeClass &c)
```

```
};
```

```
SomeClass o;
```

```
cout<<o<<endl;           // op<< ( op<< ( cout, o ), endl );
```

```
cin>>o;                   // op>> ( cin, o );
```

- warum friend ?
- warum i/o-stream Referenzen?
- warum SomeClass Referenzen?

## 2. Klassen in C++

### Überladung von `new` und `delete`

#### 1. Replacement der impliziten globalen Operatoren

sämtliche Anforderungen und Freigaben von dynamischem Speicher nutzt dann diese: tiefer Eingriff in Laufzeitsystem, nichts für den Gelegenheitsprogrammierer

```
// Definition einer der impliziten Operationen
void* operator new(std::size_t) throw(std::bad_alloc);
void* operator new[](std::size_t) throw(std::bad_alloc);
void operator delete(void*) throw();
void operator delete[](void*) throw();
void* operator new(std::size_t, const std::nothrow_t&) throw();
void* operator new[](std::size_t, const std::nothrow_t&) throw();
void operator delete(void*, const std::nothrow_t&) throw();
void operator delete[](void* , const std::nothrow_t&) throw();
```

## 2. Klassen in C++

### 1. Replacement der impliziten globalen Operatoren

```
T* t = new T;           // ::operator new(sizeof(T)); !  
delete t;              // ::operator delete(t);  
t = new T[n];          // ::operator new[](sizeof(T)*n); !  
delete[] t;           // ::operator delete[](t);
```

```
T* t = new (std::nothrow) T; // returns 0 if it fails  
delete(std::nothrow) t;  
t = new (std::nothrow) T[n]; // returns 0 if it fails  
delete[] (std::nothrow) t;
```

! throws `std::bad_alloc` if it fails

## 2. Klassen in C++

### 2. Neudefinition von globalen Operatoren

```
void* operator new/new[] (std::size_t, weitereParameter);  
void operator delete/delete[] (void*, weitereParameter);
```

außer den sog. placement-Operationen, die nicht displaceable sind:

These functions are reserved, a C++ program may not define functions that displace the versions in the Standard C++ library.

```
void* operator new/new[] (std::size_t, void*);  
void operator delete/delete[] (void*, void*);  
...  
char place[sizeof(Something)];  
Something* p = new (place) Something();  
delete (place) p;
```
